BACKGROUND OF THE INVENTION

10 1. Field of Invention

 This invention relates to the field of positron emission
tomography (PET). More specifically, the present invention is related
to a device and method for improving PET resolution through on-line
correction of patient motion.

15 2. Description of the Related Art

 In the art of PET detection, it is known that the resolution of a
scan is in part dependent upon the amount of motion of the patient
during the scan, and specifically the motion of the portion of the body
being scanned. It is known that typical PET scans last from fifteen
20 (15) minutes to three (3) hours. Ideally, if the patient could lie
motionless during a PET scan, a high resolution PET system such as
the CTI Pet Systems, Inc., EXACT HR+ is capable of 4 to 5 mm 3-D

image resolution. However, if the patient or object in the field of view (FOV) does not remain stationary, the PET image is blurred.

Practically speaking, inadvertent or disease-induced patient motion over the course of the scan currently blurs the 4 to 5 mm resolution to a far less effective 10 to 15 mm or worse.

Recent work has shown that techniques exist for tracking patient motion during the PET scan. B. J. Lopresti et al., *Implementation and Performance of an Optical Motion Tracking System for High Resolution Brain PET Imaging*, IEEE Transactions on Nuclear Science, Vol. 46, No. 6, 2059-2067 (Dec. 1999), shows effective tracking of patient head motion to all 6 degrees of 3-D movement. Specifically, they show tracking of the X-, Y-, and Z-offsets to an accuracy of fractions of a millimeter, as well as yaw, pitch, and roll to acceptable angular accuracy. Encouraged by Lopresti's effort, the industry is currently moving toward both partial and more complete analytical solutions to the blurring problem. Partial solutions include gating the PET data into time slices during which the patient is shown to be more stationary. In more complete solutions the measured head position is applied to small time slice groups of PET data or even to individual detector-pair event PET data. These solutions each apply a correction for patient motion after the PET scan has completed. The most likely application of the more complete correction is a list mode approach in which all the raw PET data is collected in a computer disk file. After the PET scan completes the data is reprocessed. While this event-by-event list mode approach corrects for the motion of, for example, a patient's head, the

reprocessing of the file data is a time consuming task.

In clinical PET applications, economic pressures demand high patient throughput without compromise to ease of use. The aforementioned list mode approach to motion de-blurring is problematic in view of these economic pressures in that more operator interaction and unacceptably long processing times are required. Either the data that is stored for reprocessing must be moved to a separate processor, or the data is reprocessed on the computer used for scanning. For a typical scan of 30-45 minute duration, reprocessing the data requires 30 minutes to 3 hours of scanner time (equivalent to approximately one to six additional scans) or an independent computing system. Taking this further, if the PET scanner is to be used almost continuously for scanning only, it will be seen that several independent computing systems are required to reprocess the data collected in a most time-efficient manner.

Typically, with respect to PET, the skull and brain are considered a single, rigid object. However, whole body PET scans also suffer from a lack of correction for motion. While problems limit effectiveness compared to brain scans, gross motions of the whole human body may also be de-blurred. PET cardiac gating is one example of a well-known but crude method to compensate for the motion of the heart during a PET scan. Difficult technical challenges remain to more effectively correct for the relative motions between and within individual organs such as, among others, the heart, lungs, liver, and lymph nodes.

Another known obstacle to on-line motion correction in the

context of most existing PET applications is on-line normalization. In standard PET, on-line histogramming permits an accumulating tally of true events to be recorded in computer memory bins. One bin is typically reserved for each line of response (LOR) or small group of LORs. Histogramming adds or subtracts unity to a designated memory bin for each prompt or delayed event. Normalization serves to compensate for variations in detector pair efficiency by scaling the bin values. This scaling is typically applied after histogramming completes and is almost never applied in any on-line or real-time fashion. To apply normalization in real time for typical human PET requires somewhat more complex electronic systems than are in typical use today. These on-line systems must rapidly add or subtract scalar values instead of unity.

Mathematical techniques for transformation from one 3-D coordinate system to another are well known. In Schaum's *Mathematical Handbook* are listed equations for translation and rotation from one 3-D coordinate system (x, y, z) to another (x', y', z'). Representative equations are as follows:

$$x' = d_{xx} * x + d_{xy} * y + d_{xz} * z + X \quad (1)$$

$$y' = d_{yx} * x + d_{yy} * y + d_{yz} * z + Y \quad (2)$$

$$z' = d_{zx} * x + d_{zy} * y + d_{zz} * z + Z \quad (3)$$

where:

X, Y, and Z are translational offsets from the coordinate system

(x, y, z) to the coordinate system (x', y', z') ;

d_{xx} , d_{xy} , and d_{xz} are direction cosines between the x -, y -, and z -axes and the x' axis, respectively;

d_{yx} , d_{yy} , and d_{yz} are direction cosines between the x -, y -, and z -axes and the y' axis, respectively; and

d_{zx} , d_{zy} , and d_{zz} are direction cosines between the x -, y -, and z -axes and the z' axis, respectively.

These three equations require nine multiplication operations and three operations involving the addition of four input variables.

The known digital electronic technique of pipelining is applied to arithmetic operations such that the speed of the electrical circuit is limited not by the whole computation but instead by the slowest individual piece of the computation. See *Introduction to Computer Architecture* by H.S. Stone, 1975, page 386, Section 9.3, "Pipelining as a Design Principle". However, such technique has not been shown in the prior art to be successful in the environment of on-line correction of patient data in a PET scan to account for patient motion.

Therefore, it is an object of the present invention to employ pipelining to reduce the throughput time of patient data to allow for on-line, real time correction for patient motion in a PET scan.

Further, it is an object of the present invention to provide a device whereby as each PET coincidence event is detected, each line of response (LOR) is re-mapped or rebinned in real time from a stationary 3-D reference space of the PET detector array into a virtual 3-D reference space which moves dynamically with the patient.

BRIEF SUMMARY OF THE INVENTION

Other objects and advantages will be accomplished by the present invention which serves to apply a correction for patient motion in an on-line and real-time manner. The present invention further provides a means whereby as each PET coincidence event is detected, each line of response (LOR) is re-mapped or rebinned in real time from a stationary 3-D reference space of the PET detector array into a virtual 3-D reference space which moves dynamically with the patient. On-line normalization is also applicable to properly histogram events which are corrected for patient movement.

The present invention incorporates a core hardware pipelining architecture to perform the transformation between 3-D coordinate spaces as required. A first digital pipeline latch is provided for receiving coincidence event and patient position data as it is collected by the PET scanner. A bank of multiplier circuits receives the PET scan data. Each multiplier circuit receives and multiplies a respective portion of each data set simultaneous with each of the other multiplier circuits. The product of each multiplier circuit is output to a second digital pipeline latch. The data is then passed to a bank of adders, each of which supports four input variables.

While data for a specific LOR and a current object orientation are input to the first digital pipeline latch, processing for a different LOR and an earlier object orientation (limited to the 3 translation offsets, X Y Z) are stored in the second digital pipeline latch. Additionally, fully transformed coordinates from a third LOR are loaded into a third digital pipeline latch. As the banks may each

complete their respective tasks under a threshold time limit, the
pipelining technique permits the entire 3-D transformation for the
“AB” gamma coincidence detector pair to take place in real time.

In event-by-event normalization, a scalar value typically in the
range of 0.01 to 100 is added to (or subtracted from) the indicated
projection space bin value for each LOR prompt (or delayed). For on-
line correction of object motion, the normalization is applied in an on-
line fashion. The result of on-line normalization is that the final total
projection bin values are scaled to properly correct for variations in
detector efficiency and dead-time.

BRIEF DESCRIPTION OF THE DRAWING

The above mentioned features of the invention will become
more clearly understood from the following detailed description of the
invention read together with the drawing in which:

FIG. 1 is a schematic of the core hardware pipelining
architecture for performing on-line correction of patient motion in
three-dimensional positron emission tomography;

FIG. 2 illustrates a schematic representation of an example on-
line computation of the composite normalization scalar value; and

FIG 3 illustrates a schematic representation for on-line
weighted
histogramming.

DETAILED DESCRIPTION OF THE INVENTION

A device and method for on-line correction of patient motion in

three-dimensional positron emission tomography (3D PET) incorporating various features of the present invention is illustrated generally at **10** in the figures. The device for on-line correction of patient motion in 3D PET, or device **10**, is designed to apply a
5 correction for patient motion in an on-line and real-time manner. Moreover, the device **10** provides a means whereby as each PET coincidence event is detected, each line of response (LOR) is re-mapped or rebinned in real time from a stationary 3-D reference space of the PET detector array into a virtual 3-D reference space which
10 moves dynamically with the patient.

Discussion of the present invention will be directed primarily toward correction of motion of the patient's head. However, it will be understood the present invention is applicable to other portions of a patient's body as well. As discussed previously, with respect to PET,
15 the skull and brain are typically considered a single, rigid object. Accordingly, correction for subtle patient head motion is effective for typical PET operation. However, whole body PET scans also suffer from a lack of correction for motion. Accordingly, it is within the scope of the present invention to track and correct for the gross
20 motions of the human as a single rigid object or as a collection of rigid objects. For example, it is foreseeable by one skilled in the art that the present invention, if replicated within each PET device, be used to differentially track the upper chest and hips as two separate rigid bodies. Similarly, the present invention may be used to simultaneously
25 track the head, upper chest, hips, upper arm, lower leg, etc.

For correction of single rigid body motion in PET, two

coordinate spaces are defined. A detector space (x, y, z) represents the coordinates fixed in relation to the 3-D array of PET detectors. An object space (x', y', z') represents the virtual 3-D coordinates fixed in relation to an object in the FOV. For illustrative purposes of the present invention, the object in the FOV is the patient's head. For any given PET coincidence event, a pair of crystal locations given in x-, y-, z- coordinates represents a detector-pair LOR. The first, or "A", crystal of a coincidence pair "AB" is referenced as residing in the unique detector location (x_a, y_a, z_a). The second, or "B" crystal is referenced as residing in detector location (x_b, y_b, and z_b).

At the beginning of the scan the object 3-D coordinate space is arbitrarily defined to be the same as that defined for the detector space. Specifically, the nine values X, Y, Z, d_{xy}, d_{xz}, d_{yx}, d_{yz}, d_{zx}, and d_{zy} from Eqs. 1-3 are all zero and the values d_{xx}, d_{yy}, and d_{zz} are all unity. As the scan progresses and object motion occurs, the translation offsets and direction cosine values vary. In order to correct for the motion of the object relative to the detector array, object coordinates are calculated for the two crystal locations in real time. The "A" detector location in object space is (x'_a, y'_a, z'_a). The "B" location in object space is (x'_b, y'_b, z'_b). The transformation equations, Eqs. 1-3 listed above, are applied both for the "A" detector position and the "B" detector position. Transformation of "A" detector location from detector space to object space is as follows:

$$x'_a = d_{xx} * x_a + d_{xy} * y_a + d_{xz} * z_a + X \quad (1a)$$

$$y'_a = d_{yx} * x_a + d_{yy} * y_a + d_{yz} * z_a + Y \quad (2a)$$

$$z_a' = d_{zx} * x_a + d_{zy} * y_a + d_{zz} * z_a + Z \quad (3a)$$

Likewise, transformation of "B" detector location from detector space to object space is as follows:

$$x_b' = d_{xx} * x_b + d_{xy} * y_b + d_{xz} * z_b + X \quad (1b)$$

$$y_b' = d_{yx} * x_b + d_{yy} * y_b + d_{yz} * z_b + Y \quad (2b)$$

$$z_b' = d_{zx} * x_b + d_{zy} * y_b + d_{zz} * z_b + Z \quad (3b)$$

As current state-of-the-art PET systems detect and generate up to twelve million AB pairs per second, the task is to calculate these 2 transformation equation sets every 83 nanoseconds.

Illustrated in FIG. 1 is a diagram of the 3-D transformation hardware pipelining architecture **10** of the present invention. A first digital pipeline latch **12** is provided for receiving data as it is collected by the PET scanner. A bank of multiplier circuits **14** receives the PET scan data. Each multiplier circuit **14** receives and multiplies a respective portion of the current LOR and positional data set simultaneously with each of the other multiplier circuits **14**. Thus, the multiplier circuits **14** collectively function simultaneously. In the preferred embodiment, each multiplier circuit **14** performs its computation in no more than 83 ns. Illustrated are 18 multiplier circuits **14** for providing 18 integers. The product of each multiplier circuit **14** is output to a second digital pipeline latch **16**. Also, the X, Y & Z translational offset variables are passed from the first latch **12** to the second **16**. From the second latch **16**, the data set is then passed to

a bank of adders **18**, each of which supports four input variables. Each input variable consists of at least twelve bits. Illustrated are six adders **18**. The adders **18** also operate simultaneously and in less than 83 ns.

While a specific LOR and a current object orientation are input to the first digital pipeline latch **12**, processing for a different LOR and an earlier object X, Y and Z offset are stored in the second digital pipeline latch **16**. Additionally and simultaneously, fully transformed (x_a' , y_a' , z_a' , x_b' , y_b' , z_b') coordinates from a third LOR are loaded into a third digital pipeline latch **20**. As the banks shown may each complete their respective tasks in 83 ns or less, the pipelining technique permits the entire 3-D transformation for the AB pair to take place on a sustained basis of twelve million events per second.

In addition to on-line 3-D coordinate transformation, on-line normalization is required for effective motion correction in PET. In typical PET practice, normalization is required and applied after histogramming. For this normalization, a scalar value, typically in the range of 0.001 to 100, is determined and applied to the already histogrammed projection bin data. These scalar values are determined to correct for various points of detector nonuniformity. These points of nonuniformity include variations in detector-to-detector sensitivity, dead-time losses, and the like. In some PET systems, an array of scalar values is produced and maps one-to-one with the array of projection bins. Here each final value in the scalar array is computed as the product of individual normalization correction values. Other PET systems, taking advantage of inherent patterns of uniformity and predictability, may effectively apply normalization correction by

processing a much smaller array of normalizing scalar values. For example, PET tomographs which rotate have very uniform sensitivity among the groups of projection bins with equal radial distance from the FOV center. Also, PET tomographs which employ continuous bed motion enjoy very uniform sensitivity from projection bin to projection bin along the FOV axis. This uniformity comes as a result of each and every FOV plane being serviced by each and every tomographic projection bin. In addition, predictable patterns of detector sensitivity exist across the transaxial extent of the FOV. Such patterns of detector sensitivity allow a small list of scalar values to correct for this variation among a very large number of projection bins. In the present invention, the final scalar values are computed as the product of these various normalization component values.

In typical PET practice, each composite scalar value is simply applied as a multiplication to the respective bin values and only the resulting products of bin values and scalar values are used for further data processing, such as for image reconstruction. In contrast, on-line normalization must be applied as a part of a "weighted" histogramming process. For systems employing weighted histogramming with on-line normalization, histogramming no longer consists of the addition or subtraction of unity to/from respective projection bins. Instead, weighted histogramming with on-line normalization consists of the addition or subtraction of scalar integer values.

In addition to the 3-D transformation hardware circuit described in FIG. 1, FIGS. 2 and 3 illustrate circuits which support weighted histogramming with on-line normalization. FIG. 2 illustrates

a schematic representation of an example of on-line computation of the composite normalizing scalar value. Three digital pipeline stages are shown supporting two processing stages. Prior to 3-D translation, LOR event data in the form of detector index pairs is input into the first pipeline latch **24**. The first processing stage shown serves to provide a transaxial geometric correction value for each event processed. A simple memory circuit **26** serves as a look-up table to provide, within the maximum threshold time (e.g., 83 ns) the indicated integer geometric correction value (GCV) for this event. This correction value is passed on to the second pipeline latch **28** with the remainder of the LOR event information. In the second processing stage, memory circuit **30** also serves as a look-up table. The memory circuit **30** is updated periodically to represent current integer dead time correction values (DCV). The memory **30** is indexed on a coincidence ring basis to provide the indicated DCV for each event. In addition, the second processing stage performs an integer multiply, as illustrated at **32**. The purpose of the multiplication is to combine the incoming correction integer value with the locally provided value so that a single integer correction value may be output. This multiplication is also required by any subsequent processing stages (not shown) which provide any additional correction values which may be required.

FIG 3 illustrates a circuit representation for on-line weighted histogramming. A real-time LOR information packet including the respective bin address and normalizing integer value is input to a latch **38**. This information is latched and then applied to the RAM array **40**. The RAM array **40** contains the projection space bins undergoing the

histogramming process. As each LOR packet arrives, a RAM controller circuit 42 sequences through the following READ/MODIFY/WRITE operation.

- 5 1. Read from RAM array 40 the current bin value indexed by the bin address.
2. Apply the bin value produced by the RAM array 40 together with the normalization value for this LOR packet to the adder circuit 44.
- 10 3. Write the output of the adder circuit 44 to the same bin address used in 1.

At the end of the data acquisition, the completed projection data set in the RAM array 40 is read and output for further processing.

From the foregoing description, it will be recognized by those skilled in the art that a device for on-line correction of patient motion in 3D PET offering advantages over the prior art has been provided. Specifically, the device is designed to apply a correction for patient motion in an on-line and real-time manner. The device provides a means whereby as each PET coincidence event is detected, each line of response (LOR) is re-mapped or rebinned in real time from a stationary 3-D reference space of the PET detector array into a virtual 3-D reference space which moves dynamically with the patient. The de-blurring of the PET data is accomplished through the combination of 3-D translation, normalization and weighted histogramming.

While a preferred embodiment has been shown and described, it will be understood that it is not intended to limit the disclosure, but rather it is intended to cover all modifications and alternate methods

1970	1971	1972	1973	1974	1975	1976	1977	1978	1979	1980	1981	1982	1983	1984	1985	1986	1987	1988	1989	1990	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025	2026	2027	2028	2029	2030	2031	2032	2033	2034	2035	2036	2037	2038	2039	2040	2041	2042	2043	2044	2045	2046	2047	2048	2049	2050	2051	2052	2053	2054	2055	2056	2057	2058	2059	2060	2061	2062	2063	2064	2065	2066	2067	2068	2069	2070	2071	2072	2073	2074	2075	2076	2077	2078	2079	2080	2081	2082	2083	2084	2085	2086	2087	2088	2089	2090	2091	2092	2093	2094	2095	2096	2097	2098	2099	2100	2101	2102	2103	2104	2105	2106	2107	2108	2109	2110	2111	2112	2113	2114	2115	2116	2117	2118	2119	2120	2121	2122	2123	2124	2125	2126	2127	2128	2129	2130	2131	2132	2133	2134	2135	2136	2137	2138	2139	2140	2141	2142	2143	2144	2145	2146	2147	2148	2149	2150	2151	2152	2153	2154	2155	2156	2157	2158	2159	2160	2161	2162	2163	2164	2165	2166	2167	2168	2169	2170	2171	2172	2173	2174	2175	2176	2177	2178	2179	2180	2181	2182	2183	2184	2185	2186	2187	2188	2189	2190	2191	2192	2193	2194	2195	2196	2197	2198	2199	2200	2201	2202	2203	2204	2205	2206	2207	2208	2209	2210	2211	2212	2213	2214	2215	2216	2217	2218	2219	2220	2221	2222	2223	2224	2225	2226	2227	2228	2229	2230	2231	2232	2233	2234	2235	2236	2237	2238	2239	2240	2241	2242	2243	2244	2245	2246	2247	2248	2249	2250	2251	2252	2253	2254	2255	2256	2257	2258	2259	2260	2261	2262	2263	2264	2265	2266	2267	2268	2269	2270	2271	2272	2273	2274	2275	2276	2277	2278	2279	2280	2281	2282	2283	2284	2285	2286	2287	2288	2289	2290	2291	2292	2293	2294	2295	2296	2297	2298	2299	2300	2301	2302	2303	2304	2305	2306	2307	2308	2309	2310	2311	2312	2313	2314	2315	2316	2317	2318	2319	2320	2321	2322	2323	2324	2325	2326	2327	2328	2329	2330	2331	2332	2333	2334	2335	2336	2337	2338	2339	2340	2341	2342	2343	2344	2345	2346	2347	2348	2349	2350	2351	2352	2353	2354	2355	2356	2357	2358	2359	2360	2361	2362	2363	2364	2365	2366	2367	2368	2369	2370	2371	2372	2373	2374	2375	2376	2377	2378</
